# Introduction

This is a manual for version 2 of XCEDE (XML-based Clinical and Experimental Data Exchange). XCEDE 2 is an extensible schema designed to enable the transfer and storage of several types of scientific data and metadata including (but not limited to) clinical, demographic, behavioral, physiological and image data. The target audience for this manual is anyone who is interested in using or learning more about XCEDE 2. This manual will serve as both a tutorial and as a reference.

Though the schema was designed in the context of neuroscientific projects, the structure of the schema is quite generic and can be applied as is to a wide variety of scientific disciplines.

## 1. Manual structure

This manual has two parts. Part I describes the various components of XCEDE 2 and describes the specification in some detail. Part II is a more practical guide to the use of XCEDE 2, providing guidance to those users who wish to extend the schema to represent project-specific metadata, or integrate XCEDE 2 into software applications and services.

## 2. Development

XCEDE 2 development started as an effort to "harmonize" the uses of XML within the BIRN (Biomedical Informatics Research Network) [BIRN] testbeds and collaborators within the neuroscientific community. The feedback from these discussion sessions led to an initial prototype (based on XCEDE 1.0) of a next-generation schema. Over the course of four months of daily teleconferences, the first public release of XCEDE 2 took form.

XCEDE 2 has its origins in various XML schemas developed for collaborative neuroinformatics projects, including:

fMRI Data Center schema	a general scientific metadata storage framework.
XNAT (Extensible Neuroimaging Toolkit)	database and web service designed to facilitate management and exploration of neuroimaging and related data.
BIAC XML Header schema	provides a format-agnostic interface to image data and is the basis for the <i>binary data resource</i> in XCEDE 2.0.
BIRN Data Provenance schema	records the history of processing steps and is the basis for the <provenance> element in the schema.
XCEDE (1.0) SPM Toolbox	provides a general framework (and MATLAB interface) for storage and retrieval of thresholded statistical parametric maps and associated anatomical labels.

The primary developers of XCEDE 2 are (in alphabetical order): Syam Gadde (Duke University), Jeff Grethe (University of California, San Diego), Dave Keator (University of California, Irvine), and Dan Marcus (Washington University, St. Louis), all of whom have received support for this project through various BIRN testbeds.

## 3. For More Information

XCEDE is an evolving format -- later versions will be informed by feedback from users and developers. The latest schema and related information can be found on the project's web page at <http://www.xcede.org/>.

---

# Part I. XCEDE 2 Core Specification

This section of the XCEDE 2.0 manual focuses on the high-level structure and major components of the XCEDE 2 Core schema. Each chapter contains a description of the component and provides examples of usage. The examples in this section are largely drawn from neuroscientific metadata, as this data served as the driving force behind development. However, these examples are by no means comprehensive; the schema was designed to be generally applicable (and extensible) to many types of scientific data, and this manual by necessity focuses on only a few.

---

# Chapter 1. Structure and Conventions

## 1.1. The XCEDE 2 Dataset

An XCEDE 2 Dataset is a data repository (stored in files, databases, or using other storage mechanisms) that can be represented as a collection of one or more XML documents, each of which validates against the XCEDE 2 XML schema (Appendix A). The XCEDE 2 specification does not prescribe any particular mechanism by which these documents are located, stored, grouped, or linked, though XCEDE 2 allows certain XML elements to link to other target elements and to optionally specify URLs as hints as to the location of the documents containing these targets.

For example, a given XCEDE 2 dataset may be stored as a single XML document, or a collection of files in a single directory on a file system, or may be distributed within a hierarchical directory structure (which may or may not reflect the structure of the data within), or may be stored within a database accessible by query through a web interface. The semantics of the dataset should be fully reflected in the XML representation, and should not be dependent on how the dataset is stored.

A schema-compliant XCEDE 2 document must be a valid XML 1.0 document [XML10], and must have one root element, `<XCEDE>`, which (like all other XCEDE 2 elements) is in the XML namespace `http://www.xcede.org/xcede-2`.

Several major components of the XCEDE 2 dataset are represented as children of the XCEDE root element. These components include:

- **Experiment hierarchy.** The components in the experiment hierarchy are represented by elements `<project>`, `<subject>`, `<visit>`, `<study>`, `<episode>`, `<acquisition>`. These are described in more detail in Chapter 2.
- **Analyses.** The `<analysis>` element encapsulates metadata about data that is derived from one or more inputs, whose data is represented by other XCEDE elements. See Chapter 9.
- **Protocols.** Structures to describe the expected course of an experimental paradigm are provided by the `<protocol>` element. See Chapter 7.
- **Data resources.** Represented by the element `<resource>`, these point to external files which store actual data. See Chapter 3.
- **Data.** The element `<data>` is used to store actual data within the XML document. Examples include *events* (Chapter 6) and *assessments* (Chapter 8).

Other XCEDE components appear as subcomponents of other XCEDE structures:

- **Data provenance.** The `<provenance>` element appears in the types `analysis_t` (on which the `<analysis>` element is based) and `dataResource_t` (one of the available data models for the top-level `<resource>` element). See Chapter 5.
- **Comments and annotations.** The `<commentList>` and `<annotationList>` provide a mechanism to store descriptive text regarding the real-world entities or concepts represented by the associated XML element, or about the stored XML element itself. These are available in all elements based on `abstract_container_t`, which includes all the hierarchy elements and `<analysis>`.
- **Informational resources.** These point to documentation that may illuminate aspects of the data, data collection, protocol, etc. -- these might include peer-reviewed publications, equipment manuals,

and others. Informational resources are represented in the type `informationResource_t` which is used in the `<resourceList>` element in `abstract_container_t` (as with the comments and annotations).

- **Terminology.** Various elements in XCEDE 2 include the attribute group `terminology_ag` or use the type `terminologyString`, which allow the user to associate them with terms from particular nomenclatures/ontologies. For example, a subject's `<species>` may refer to a standard term listed in a well-known public nomenclature. See Chapter 10.

## 1.2. XCEDE 2 Schema conventions

The XCEDE XML document structure is defined using W3C XML Schema language [XMLSchema10]. With a few exceptions, the XCEDE 2 XML schema subscribes to the following conventions and best practices.

### Naming and capitalization.

- Element and attribute names are alphanumeric (`<project>`). All letters are lowercase, with the exception of acronyms, which are uppercase (`<XCEDE>`, `projectID`), and, in multi-word names, the initial letters of the second and following words which are capitalized (`<dataResourceRef>`). For the purposes of this rule, ID (for "identifier") is considered an acronym.
- Schema type names (which do not appear in XML instance documents except in `xsi:type` attributes) follow the same naming conventions as element and attribute names, but have the `_t` suffix (`analysis_t`). If the type is "abstract", then it has an `abstract_` prefix (`abstract_container_t`).
- Attribute group names (which do not appear in XML instance documents) follow the same naming conventions as element and attribute names, but have the `_ag` suffix (`allLevelExternalIDs_ag`).

### Schema best practices.

- Follow the schema versioning best practices recommended by Roger Costello in [CostelloSchemaVersioning]. Some of the implications are listed below:
  - The XCEDE namespace will change for major versions, but not minor versions. So, the namespace is as follows: `http://www.xcede.org/xcede-major_version`. For example: `http://www.xcede.org/xcede-2`
  - XSD files will be named `xcede-version-domain`. For example: `xcede-2.0-core.xsd`
  - All elements should have a corresponding named `complexType`. For example: `<project>` is of type `project_t`.
  - The schema prescribes that some elements precede or follow other elements -- document creators should follow this strictly. However, applications should be written without expecting a particular element order, in case later versions of the schema change the order of elements. That is, be conservative in what you write, but liberal in what you accept.

This is not to say that element order is not important -- the relative order of multiple elements with the same name should be preserved and can be relied upon by applications. So, if the schema specifies the content model of an element to have multiple `<A>` children and then multiple `<B>` children, applications should treat a dataset the same whether all the `<B>` children came first or second. The corollary is that the semantics of an XCEDE element must not depend on the order in which differently-named children are presented in the document.

### **Document validation.**

- The structure of an XCEDE document can be validated using the XCEDE 2 Core schema. Several XML Schema validators are available to perform this task. Validating against the schema will ensure that generic XCEDE 2 parsers can read the document.

Users may wish to run *content-based* validation of XCEDE document, for example, to make sure that "MR" image metadata stored in an XCEDE document have certain required fields such as TR, TE, magnet field strength, etc. This kind of validation is not possible using XML Schema. However, other content-based schema languages exist for this purpose, most notably Schematron [Schematron]. As long as the XCEDE 2 Core schema is structurally sufficient to represent data for a given project or type of data, using a content-based schema language such as Schematron allows users to restrict or "specialize" the content of XCEDE documents without needing to modify or extend from the XCEDE 2 Core schema itself.

---

# Chapter 2. Experiment Hierarchy

## 2.1. Overview

As illustrated in Figure 2.1, the XCEDE experiment hierarchy consists of several *levels* representing divisions of experiment data at various granularities. Elements at each level contain level-specific "info" elements, whose schema types may be derived to store experiment-specific or data modality-specific metadata. The linking mechanism between levels is flexible enough to support the omission of levels if the schema user finds them unnecessary.

**Figure 2.1. XCEDE hierarchy**

## 2.1.1. Hierarchy Levels

In the typical intended usage, a *project* is the top-level division of experiment data, and represents a research project which collects and analyzes data from one or more *subjects* which are divided (within the project) into *subject groups*. A subject may be a member of multiple research projects, and it is the subject group that maintains and distinguishes the mappings between subjects and research projects.

A *visit* may represent a subject's appearance at an experiment "site" (for collaborative projects, this could be the institution or lab at which the data is being collected or analyzed). A visit, may be further subdivided into one or more *studies*, each of would consist of one or more data collection *episodes*.

Visit and study are more or less arbitrary divisions of the data that exist for convenience, and do not in themselves have any inherent meaning as far as the schema is concerned. However, an episode is intended to represent a unit of data collection over a given time interval, and should contain one or more data *acquisitions*, which should be understood to occur simultaneously over the duration of the episode. So, for example, an episode in an fMRI study may encapsulate the acquisition of a time-series of volume images from an MR scanner, as well as other acquisitions of behavioral or physiological data; all these (simultaneous) acquisitions would be stored as part of the same episode.

At first thought, it would be natural to represent the experiment hierarchy as described as a traditional XML hierarchy, where higher-level elements encapsulate lower-level elements as child elements. However, in XCEDE, all level elements (<project>, <visit>, etc.) are stored as children of the root <XCEDE> element. Links between levels are implicit in the level IDs assigned to each element and propagated to elements in lower levels. The great benefit of this approach is that applications are easier to write because all major elements are stored in the same place (under the XCEDE root element), and that XCEDE documents can be merged by merely concatenating the lists of top-level elements under a single XCEDE root element. Another advantage is to allow users of the schema to omit levels merely by omitting the unnecessary elements and IDs/links.

## 2.1.2. IDs and Linking

Any level element can be the target of a link from another element. In addition, most level elements are implicitly linked to "ancestor" level elements. Both these types of links are created by specifying one or more *level IDs* that together uniquely describe a target level element.

Every level element has a set of these level IDs, composed of the element's own ID attribute, plus its "ancestor" ID attributes, indicating which higher-level elements have this element in their scope. For example, the <visit> element contains subjectGroupID, subjectID, and projectID attributes.

For example, a link to a visit element may specify visitID, subjectID, subjectGroupID, and projectID attributes, and a level attribute with the value visit, indicating that this link is to a visit element. An application resolving this link will search for a visit element in the XCEDE 2 dataset whose attributes match those specified in the link (the visitID attribute is matched against the ID attribute in the visit element). Level ID attributes not specified in the link should match any value, but a link must specify enough of these IDs match at most one level element.

The elements that can link to any level element are <catalog>, <resource>, and <data> (children of the <XCEDE> root element), <inputRef> and <outputRef> (children of the <analysis> element). Level elements (except for <project> and <subject>, which are at the top of the experiment hierarchy) can be implicitly linked to ancestor elements using the attributes provided.

## 2.2. Examples

### 2.2.1. Metadata hierarchy

The metadata hierarchy illustrated in Figure 2.1 can be represented in XCEDE as shown in Figure 2.2 (only those elements/attributes relevant to linking are shown; the actual metadata contents of the elements are omitted for space).

**Figure 2.2. Metadata hierarchy instance**

```
<XCEDE xmlns="http://www.xcede.org/xcede-2">
  <project ID="A">
    <projectInfo>
      <subjectGroupList>
        <subjectGroup ID="X">
          <subjectID>1</subjectID>
          <subjectID>2</subjectID>
        </subjectGroup>
      </subjectGroupList>
    </projectInfo>
  </project>
  <project ID="B">
    <projectInfo>
      <subjectGroupList>
        <subjectGroup ID="Z">
          <subjectID>3</subjectID>
        </subjectGroup>
      </subjectGroupList>
    </projectInfo>
  </project>
  <subject ID="1" />
  <subject ID="2" />
  <subject ID="3" />
  <visit ID="1"
    projectID="A" subjectID="1" subjectGroupID="X" />
  <study ID="MR scan"

  <!-- ... etc. ... -->
</XCEDE>
```

---

# Chapter 3. Binary Data Resources

## 3.1. Overview

The XCEDE 2 *Binary Data Resource* component is used to provide a generic interface to a binary data stream stored in one or more external files. Any of the binary data resource types described in this chapter can be used anywhere an `abstract_resource_t` is called for (with the appropriate `xsi:type` attribute); in the current XCEDE schema, these locations are the top-level `<resource>` element and the `<dataResource>` child element of `<acquisition>`.

XCEDE provides multiple layers of derived types to store more specialized information about the binary data. The base type and each of the derived types are described in turn.

**abstract\_resource\_t.** The abstract base type `abstract_resource_t` provides a few elements and attributes that are especially important for binary data resources. In particular, the `<uri>` element and its `offset` and `size` attributes point to a “chunk” of data stored in an external file. A series of `<uri>` elements define a stream of data that may be described in greater detail by the data types described below.

**binaryDataResource\_t.** This type derives from `abstract_resource_t` and allows an application to interpret the data stream as a sequence of data items with a given data type (`<elementType>`) and byte order (`<byteOrder>`).

**dimensionedBinaryDataResource\_t.** The data stream, until now, could only be interpreted as a one-dimensional sequence. This type provides `<dimension>` elements that allow the data stream to be interpreted as a multi-dimensional array of data items. Each dimension has a `<size>` and a `<label>`, as well as the ability to discard subsets of the data in the data stream (using the `outputSelect` attribute).

**mappedBinaryDataResource\_t.** This type places the multi-dimensional array of data items represented by `dimensionedBinaryDataResource_t` into an arbitrary coordinate system.

## 3.2. Examples

Several examples of binary data are presented here, each showing the use of one of the different binary data types described in this chapter.

### 3.2.1. Basic data stream

The basic binary data resource type describes a sequence of data items. For example, consider a data file (`random_data_file.bin`) containing 2048 random 32-bit floating point numbers, stored in little-endian (least-significant-byte first) order. The `<dataResource>` describing this data is shown in Figure 3.1.

**Figure 3.1. Simple `binaryDataResource_t` example**

```
<dataResource xsi:type="binaryDataResource_t">
  <uri offset="0" size="8192">random_data_file.bin</uri>
  <elementType>float32</elementType>
  <byteOrder>lsbfirst</byteOrder>
</dataResource>
```

Note the `xsi:type` specifying that this `<dataResource>` element is of type `binaryDataResource_t`. (The `xsi:` prefix should have already been declared previously in the XML file using something similar to `xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"`)

The `<elementType>` element is restricted to one of several pre-defined strings (see the schema for details). The `<byteOrder>` element must be `lsbfirst` for little-endian data or `msbfirst` for big-endian data.

If the `<compression>` element is specified, it specifies that the file(s) pointed to by the `<uri>` elements are compressed. The content of the element should specify which type of compression (the only compression method specifically recognized by this specification is `gzip`). The size and offset attributes in the `<uri>` element always refer to the *uncompressed* data. An example of this is shown in Figure 3.2.

**Figure 3.2. `binaryDataResource_t` with compression**

```
<dataResource xsi:type="binaryDataResource_t">
  <uri offset="0" size="8192">random_data_file.bin.gz</uri>
  <elementType>float32</elementType>
  <byteOrder>lsbfirst</byteOrder>
  <compression>gzip</compression>
</dataResource>
```

As a special case, if the application does not find the file pointed to by a URI, and the `<compression>` element is *not* present, it may search for the same file with an appended `.gz` suffix, and if it exists, treat it as implicitly `gzip`-compressed data. Figure 3.3 shows how the same data in Figure 3.2 could be expressed using this alternative method. Pointing to the uncompressed version of the file (even when only the compressed version exists) allows the user to decompress or compress the data file at will, without affecting the ability of the application to read the data using the same `binaryDataResource_t`. Note that the `<uri>` and `<compression>` elements must be internally consistent. It would be an error to reference the uncompressed file `random_data_file.bin` and yet say that it was compressed using `<compression>gzip</compression>`. Likewise, explicit references to the compressed file (especially files that do not have the `.gz` suffix) must specify the compression method explicitly using the `compression` element.

**Figure 3.3. `binaryDataResource_t` with implicit compression**

```
<dataResource xsi:type="binaryDataResource_t">
  <uri offset="0" size="8192">random_data_file.bin</uri>
  <elementType>float32</elementType>
  <byteOrder>lsbfirst</byteOrder>
</dataResource>
```

## 3.2.2. Dimensioned data

Consider a camera that acquires an image using a 256x256 matrix of big-endian 32-bit signed integer voxels. This data has two spatial dimensions, which, by convention, we label `x`, and `y` (and `z` if a third spatial dimension is needed, and `t` if there is a time dimension). Figure 3.4 shows how this data might be represented.

**Figure 3.4. `dimensionedBinaryDataResource_t` example**

```
<dataResource xsi:type="dimensionedBinaryDataResource_t">
  <uri offset="0" size="262144">rawdata.img</uri>
  <elementType>int32</elementType>
  <byteOrder>msbfirst</byteOrder>
  <dimension label="x">
    <size>256</size>
  </dimension>
  <dimension label="y">
    <size>256</size>
  </dimension>
</dataResource>
```

Dimensions are ordered from fastest-moving to slowest-moving. So in the above example, the x dimension index changes on each consecutive data item, but the y dimension changes every 256 elements.

### 3.2.3. Mapped data

A “mapped” binary data resource is a (perhaps multidimensional) array of values, the matrix indices of which can be converted into a location in a given coordinate system. The location of the bounding box of the data in this space is given by specifying a location (in target-space coordinates) for the first data item, and two things for each dimension: a unit-length direction vector (in the target-space coordinate system) and the spacing between successive data items in that dimension. The transformation matrix for a three-dimensional coordinate system has the form shown in Figure 3.5. This transformation matrix converts from matrix indices  $(x, y, z)$  to a coordinate location  $(a, b, c)$ . Figure 3.6 shows how the components of a transformation of MR image data into scanner RAS (Right/Anterior/Superior) coordinates are represented in a `mappedBinaryDataResource_t`. The unit vectors for each dimension are  $(X_A \ X_B \ X_C) = (1 \ 0 \ 0)$ ,  $(Y_A \ Y_B \ Y_C) = (0 \ 1 \ 0)$ , and  $(Z_A \ Z_B \ Z_C) = (0 \ 0 \ 1)$ , and are placed in the `<direction>` elements in each `<dimension>` element. The spacing values  $(S_X \ S_Y \ S_Z) = (3.75\text{mm} \ 3.75\text{mm} \ 4\text{mm})$  are put in the `<spacing>` element in each `<dimension>`. The coordinates of the first voxel in the data are given by  $(O_A \ O_B \ O_C) = (-120 \ -120 \ -52)$ .

**Figure 3.5. Transformation matrix**

$$\begin{pmatrix} X_A & Y_A & Z_A & O_A \\ X_B & Y_B & Z_B & O_B \\ X_C & Y_C & Z_C & O_C \\ 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} S_X & 0 & 0 & 0 \\ 0 & S_Y & 0 & 0 \\ 0 & 0 & S_Z & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} i \\ j \\ k \\ 1 \end{pmatrix} = \begin{pmatrix} a \\ b \\ c \\ 1 \end{pmatrix}$$

**Figure 3.6. mappedBinaryDataResource\_t example**

```
<dataResource xsi:type="mappedBinaryDataResource_t">
  <uri offset="0" size="442368">V0001.img</uri>
  <uri offset="0" size="442368">V0002.img</uri>
  <uri offset="0" size="442368">V0003.img</uri>
  <uri offset="0" size="442368">V0004.img</uri>
  <uri offset="0" size="442368">V0005.img</uri>
  <!-- ... 135 more <uri> elements omitted for space ... -->
  <elementType>int32</elementType>
  <byteOrder>msbfirst</byteOrder>
  <dimension label="x">
    <size>64</size>
    <spacing>3.75</spacing>
    <gap>0</gap>
    <direction>1 0 0</direction>
    <units>mm</units>
  </dimension>
  <dimension label="y">
    <size>64</size>
    <spacing>3.75</spacing>
    <gap>0</gap>
    <direction>0 1 0</direction>
    <units>mm</units>
  </dimension>
  <dimension label="z">
    <size>27</size>
    <spacing>4</spacing>
    <gap>1</gap>
    <direction>0 0 1</direction>
    <units>mm</units>
  </dimension>
  <dimension label="t">
    <size>140</size>
    <spacing>2</spacing>
    <gap>0</gap>
    <datapoints>0 2 4 6 8</datapoints>
    <units>sec</units>
  </dimension>
  <originCoords>-120 -120 -52</originCoords>
</dataResource>
```

### 3.2.4. Advanced topic: split dimensions and outputSelect

A more complicated example is given by data generated by a Siemens MR scanner. In this case, the data represents a three-dimensional 64x64x32 image, stored in DICOM format. However, because the earlier versions of the DICOM format did not support three-dimensional data in one file, Siemens came upon the clever idea to “tile” the 32 two-dimensional slices across an NxN two-dimensional grid (Figure 3.7).

**Figure 3.7. A “tiled” image**

Applications may naturally want to express this data as a three-dimensional block, with columns, rows, and slices. In a conventionally-stored three-dimensional  $X \times Y \times Z$  image, the first  $X$  voxels compose the first row in the first slice, and then the next  $X$  voxels are the second row in the first slice; likewise the first  $X \times Y$  voxels are the first slice, and the next  $X \times Y$  voxels are the second slice, and so on. However, in the “tiled” image, though the first  $X$  voxels are again the first row in the first slice, the next  $X$  voxels are the first row in the second slice! At first it would seem that the dimension order has merely been switched, and specifying the labels of the dimensions as  $x$ ,  $z$ , and  $y$  would fix things. However, we only hit six slices' first rows before hitting going to the second row of the same six slices. Only after going through all the rows in this fashion in the first six slices do we go on to the next six slices.

The end result is that the dimension that we are calling the  $z$  dimension has been split in two. The two components of the  $z$  dimension are interleaved with the  $x$  and  $y$  dimensions like so:  $x$ ,  $z_1$ ,  $y$ ,  $z_2$ . The two components of the  $z$  dimension are distinguished with the `splitRank` attribute, as shown in Figure 3.8.

**Figure 3.8. Split dimension example**

```
<dataResource xsi:type="binaryDataResource_t">
  <uri offset="9240" size="589824">img0001.dcm</uri>
  <elementType>uint32</elementType>
  <byteOrder>lsbfirst</byteOrder>
  <dimension label="x">
    <size>64</size>
  </dimension>
  <dimension label="z" splitRank="1">
    <size>6</size>
  </dimension>
  <dimension label="y">
    <size>64</size>
  </dimension>
  <dimension label="z" splitRank="2">
    <size>6</size>
  </dimension>
</dataResource>
```

Applications should read this data as if it were four dimensions, and then permute the data to bring the two  $z$  dimensions together (in the order specified by `splitRank`) in the position of the highest-ranked split dimension, and the two dimensions can then be merged into one. The size of the new  $z$  dimension is the product of the sizes of the component split dimensions, so  $6 * 6 = 36$ .

You may recall that the original data was acquired as a 64x64x32 volume, but the NxN tiling representation requires that the number of tiles be the square of an integer N. One more mechanism has been added to the `<dimension>` element to accommodate the presence of data that should be disregarded: the `outputSelect` attribute (see Figure 3.9).

### Figure 3.9. `outputSelect` example

```
<dataResource xsi:type="binaryDataResource_t">
  <uri offset="0" size="589824">img0001.dcm</uri>
  <elementType>uint32</elementType>
  <byteOrder>lsbfirst</byteOrder>
  <dimension label="x">
    <size>64</size>
  </dimension>
  <dimension label="z" splitRank="1">
    <size>6</size>
  </dimension>
  <dimension label="y">
    <size>64</size>
  </dimension>
  <dimension label="z" splitRank="2" outputSelect="0 1 2 3 4 5 6 7 8 9 10 11 12 13 14
15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31">
    <size>6</size>
  </dimension>
</dataResource>
```

The `outputSelect` attribute specifies a list of indices along the given dimension (or combined dimension if it occurs on the highest-ranked component of a split dimension) that should be regarded as valid data. Data in the other indices should be ignored.

---

# Chapter 4. Catalogs

## 4.1. Overview

Catalogs in XCEDE 2 are containers of related resources, resource references, and data references. They are recursive in that catalogs can contain a list of catalogs and catalog references.

Catalogs are represented by the `catalog_t` complex type, derived from `abstract_tagged_entity_t`. The catalog child element of the root XCEDE element is of type `catalog_t`. The resources included in the catalog can be pointed to from by resource references in a number of places in XCEDE, including `analysis_t` and `acquisition_t`.

Catalogs are useful in a number of contexts. A catalog could be created, for example, to represent all of the acquisition resources associated with an episode. These catalogs could be contained within a parent catalog that represents each of the episodes in an MR study. Catalogs could also be used to represent the various resources generated as part of an analysis or uploaded and tagged by users.

A benefit of using catalogs, as opposed to linking resources directly in analysis and acquisition elements, is that the catalogs can be sent to client applications that choose not to support the full XCEDE specification.

## 4.2. Examples

**Figure 4.1. Catalog instance**

```
<XCEDE>

# Chapter 5. Provenance

## 5.1. Overview

Provenance is used to record in detail the sequence of processing and analysis steps that have been executed to create a derived image and/or measures. These details include the name and type of machine on which the executable was run, the name of the executable, and input parameters to the executable.

XCEDE-represented studies will be populated with large numbers of medical image volumes which researchers will wish to access and run various processing tools on in order to obtain derived data. This derived data, such as volumes of various brain structures, cortical thickness etc., will then be placed back into the database, linked to the original volume from which it was produced. If a researcher would like to recreate the processing steps, in order to apply it to a new data set, they will be able to obtain the information needed to download or reconstruct the tools that were used on the original data set. Information about the processing tools needs to be made available by the authors of the tools, is collected at run time by the processing scripts, and written into XCEDE.

**provenance\_t.** This type contains an ordered sequence of processing steps (`processStep_t`) that were executed to create the data that this element is contained within, which can be `dataResource_t` or an `analysis_t`.

**processStep\_t.** This type contains two attributes, ID and parent, indicating a unique ID for the step and its parent step, respectively. It includes a number of child elements that describe the conditions under which an executable was run. All of the child elements are formally optional. The following are strongly recommended: `program` The name of the executable. The version attribute is required, build number is optional. See instructions below for inserting version control content. Alternately, you can define it as a user string. `programArguments` The arguments passed into the executable. The attributes are optional, they are used to break down the full list of arguments into input and output arguments. `timestamp` The time at which the program started to run, milliseconds are optional until cross platform code can be found. `user` Who was logged in and running this executable? `hostName` The unique id of the computer running this executable. Replaces Machine from old schema. `architecture` This is the type of hardware that the processing step is run on, sun, x86, etc. `platform`: This is the operating system under which the processing step is being run. These are optional: `cvcs` Revision control repository information. Use the CVS keyword `Id`, inserted into your source code file as `$Id: chap_provenance.xml,v 1.6 2007/08/06 21:07:32 gadde Exp $` and it will be replaced with the file name, version, date of change and who changed it. Also works with SVN, but see SVN notes for enabling it. `compiler` What was used to compile this executable? Name and version. `library` The name and version of a linked library. Can be repeated as many times as necessary. This is dependent on the library in question, examples are given for VTK and Tcl and Tk. `buildTimestamp` The time stamp showing when the executable was built `package` This tag gives the overall package version, if the executable is part of a larger unit, for example, `mri_convert` is part of FreeSurfer, and the whole FreeSurfer package may have a different version number than the `mri_convert` executable that might change at a different rate. `repository` Where can the software be found? Link to a code repository or a web page. Can be extracted automatically if using SVN, via the `HeadURL` keyword.

## 5.2. Examples

## 5.3. Generating provenance XML from applications

The figure below illustrates a C code snippet (written by Nicole Aucoin and implemented in 3DSlicer) that generates provenance XML from an application. [Note: This may not be completely compliant with XCEDE2.]

```
void printAllInfo(int argc, char **argv)
{
    int i;
    struct tm * timeInfo;
    time_t rawtime;
    // yyyy/mm/dd-hh-mm-ss-ms-TZ
    // plus one for 3 char time zone
    char timeStr[27];

    fprintf(stdout, "<ProcessStep>\n");
    fprintf(stdout, "<Program version=\\"$Revision: 1.6 $\\">%s</ProgramName>\n", argv[0]);
    fprintf(stdout, "<ProgramArguments>");
    for (i = 1; i < argc; i++)
    {
        fprintf(stdout, " %s", argv[i]);
    }
    fprintf(stdout, "</ProgramArguments>\n");
    fprintf(stdout, "<CVS>$Id: chap_provenance.xml,v 1.6 2007/08/06 21:07:32 gadde Exp\n");
    time ( &rawtime );
    timeInfo = localtime (&rawtime);
    strftime (timeStr, 27, "%Y/%m/%d-%H-%M-%S-00-%Z", timeInfo);
    fprintf(stdout, "%s</TimeStamp>\n", timeStr);
    fprintf(stdout, "<User>%s</User>\n", getenv("USER"));

    fprintf(stdout, "<HostName>");
    if (getenv("HOSTNAME") == NULL)
    {
        if (getenv("HOST") == NULL)
        {
            fprintf(stdout, "(unknown)");
        }
        else
        {
            fprintf(stdout, "%s", getenv("HOST"));
        }
    }
    else
    {
        fprintf(stdout, "%s", getenv("HOSTNAME"));
    }
    fprintf(stdout, "</HostName><Platform version=\\"");
    #if defined(sun) || defined(__sun)
    #if defined(__SunOS_5_7)
    fprintf(stdout, "2.7");
    #endif
    #if defined(__SunOS_5_8)
    fprintf(stdout, "8");
    #endif
    #endif
    #if defined(linux) || defined(__linux)
    fprintf(stdout, "unknown");
    #endif
}
```

```
#endif

    fprintf(stdout, ">");
    // now the platform name
    #if defined(linux) || defined(__linux)
        fprintf(stdout, "Linux");
    #endif
    #if defined(macintosh) || defined(Macintosh)
        fprintf(stdout, "MAC OS 9");
    #endif
    #ifdef __MACOSX__
        fprintf(stdout, "MAC OS X");
    #endif
    #if defined(sun) || defined(__sun)
    # if defined(__SVR4) || defined(__svr4__)
        fprintf(stdout, "Solaris");
    # else
        fprintf(stdout, "SunOS");
    # endif
    #endif
    #if defined(_WIN32) || defined(__WIN32__)
        fprintf(stdout, "Windows");
    #endif
    fprintf(stdout, "</Platform>\n");

    if (getenv("MACHTYPE") != NULL)
    {
        fprintf(stdout, "<Architecture>%s</Architecture>\n", getenv("MACHTYPE"));
    }

    fprintf(stdout, "<Compiler version=\");
    #if defined(__GNUC__)
    #if defined(__GNU_PATCHLEVEL__)
        fprintf(stdout, "%d", (__GNUC__ * 10000 + __GNUC_MINOR__ * 100 +
        __GNU_PATCHLEVEL__));
    #else
        fprintf(stdout, "%d", (__GNUC__ * 10000 + __GNUC_MINOR__ * 100));
    #endif
    #endif
    #if defined(_MSC_VER)
        fprintf(stdout, "%d", (_MSC_VER));
    #endif
    // now the compiler name
    fprintf(stdout, ">");
    #if defined(__GNUC__)
        fprintf(stdout, "GCC");
    #else
    #if defined(_MSC_VER)
        fprintf(stdout, "MSC");
    #else
        fprintf(stdout, "UNKNOWN");
    #endif
    #endif
    fprintf(stdout, "</Compiler>\n");

    fprintf(stdout, "<Library version=\"%s\">VTK</Library><Library
version=\"unknown\">ITK</Library><Library version=\"%s\">KWWidgets</Library>\n",
VTK_VERSION, KWWidgets_VERSION);
    int major, minor, patchLevel;
    Tcl_GetVersion(&major, &minor, &patchLevel, NULL);
    fprintf(stdout, "<Library version=\"%d.%d.%d\">TCL</Library>\n", major, minor,
patchLevel);
    //fprintf(stdout, "<Library version=\"%d.%d.%d\">TK</Library>\n", major,
//minor, patchLevel);
    #ifdef USE_PYTHON
        fprintf(stdout, "<Library version=\"%s\">Python</Library>\n", PY_VERSION);
```

```
#endif
    fprintf(stdout, "<Repository>$HeadURL:
http://www.na-mic.org/svn/Slicer3/trunk/Applications/GUI/Slicer3.cxx
$</Repository>\n");
    fprintf(stdout, "<ProcessStep>\n");
    fprintf(stdout, "\n");
}
```

For the version, you can use the CVS keyword Name, inserted into your source code file as \$Name: \$ and it will be replaced with a the version tag when you check out the code with a tag:

```
cvs -r tag co [modulename]</programlisting>
```

If you are using SVN, in order to use CVS style keywords and have them be replaced with the appropriate values, you must enable the SVN repository's properties on a file by file (and keyword by keyword) basis by issuing the following command:

```
svn propset svn:keywords "Revision Id Date HeadURL" [filename.ext]
```

## 5.4. Reference

---

# Chapter 6. Events

## 6.1. Overview

*Events* in XCEDE are merely time intervals annotated with arbitrary metadata. This component can be used to represent several types of behavioral data, statistics calculated on time series data, or any other metadata whose proper interpretation requires that it be associated with a particular time interval.

An XCEDE event consists of the following:

onset	The onset (in seconds) of the time interval.
duration	The duration (in seconds) of the time interval.
type	Usage of this field is user-specified
name	Usage of this field is user-specified
units	The units of the onset and duration fields. This field is optional, and it is recommended that users of the schema prescribe an implicit unit of measurement and use it consistently. In that case, this field may be considered informational only.
values	A <i>value</i> adds named metadata to this event.

The following instance shows how each of these fields may be populated.

```
<event type="visual" name="event#1" units="sec">
  <onset>0</onset>
  <duration>2</duration>
  <value name="shape">square</value>
  <value name="shapecolor">red</value>
</event>
```

Event elements are stored within the `<data>` element of an `<acquisition>`. The `<data>` element should be of type `events_t` (using `xsi:type` — see examples below).

All onsets are relative to an arbitrary time reference. Typically, time 0 (zero) could mean the start of data acquisition. An event list may be interpreted as concurrent with data in other `<acquisition>` elements (which could be other event lists). If so, the same time reference should be used in all concurrent acquisition data.

There is no ordering constraint on events in a list. Applications should depend on using the `<onset>` elements to order the events chronologically if they so desire.

An optional `<params>` element may precede the first event in a list, and this element stores arbitrary metadata (using the same `<value>` element used above) that apply to all events in the list.

## 6.2. Examples

Figure 6.1. An event timeline

Consider the timeline shown in Figure 6.1, representing stimuli and responses in a neuroimaging study. We show in Figure 6.2 how the first 5 seconds' worth of the events might be represented in XCEDE.

**Figure 6.2. XCEDE Events example - stimulus/response data**

```

<XCEDE xmlns="http://www.xcede.org/xcede-2"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <acquisition ID="my_stimulus_response_data">
    <dataRef ID="my_events" />
  </acquisition>
  <data ID="my_events" xsi:type="events_t">
    <event type="visual">
      <onset>0</onset>
      <duration>2</duration>
      <value name="shape">square</value>
      <value name="shapecolor">red</value>
    </event>
    <event type="visual">
      <onset>2.5</onset>
      <duration>2</duration>
      <value name="shape">square</value>
      <value name="shapecolor">blue</value>
    </event>
    <event type="audio">
      <onset>0.3</onset>
      <duration>1.4</duration>
      <value name="frequency">low</value>
    </event>
    <event type="audio">
      <onset>2.0</onset>
      <duration>1.4</duration>
      <value name="frequency">low</value>
    </event>
    <event type="audio">
      <onset>3.5</onset>
      <duration>1.4</duration>
      <value name="frequency">low</value>
    </event>
    <event type="response">
      <onset>3.4</onset>
      <value name="button">1</value>
    </event>
  </data>
</XCEDE>

```

Each stimulus and each response are stored as separate event elements. Note that all the visual events appear first in the XCEDE file, then the audio events, and then the response event. This ordering is arbitrary, and the events could easily have been presented in chronological (or random!) order. The semantic interpretation of the events within an event list must not depend on their document order.

Stimulus and response data are not the only appropriate content to represent in XCEDE events. Figure 6.3 shows how quality assurance (QA) statistics for each volume/timepoint in an fMRI scan can be stored as events. Note that the time reference for the onsets is arbitrary, but if the acquisition containing the event data is contained within the same episode as other time-locked data, it should be assumed that the time reference is the same for all acquisitions within the episode, unless otherwise explicitly specified. So, for example, this QA data might be associated with MR image data in the same episode, and time 0 (zero) would by default be assumed to have the same meaning in both sets of data.

**Figure 6.3. XCEDE Events example - QA data**

```
<XCEDE xmlns="http://www.xcede.org/xcede-2"
        xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <acquisition ID="my_stimulus_response_data">
    <dataRef ID="my_events" />
  </acquisition>
  <data ID="my_events" xsi:type="events_t">
    <event>
      <onset>0</onset>
      <duration>2</duration>
      <value name="volmean">759.218</value>
      <value name="cmassx">106.781</value>
      <value name="cmassy">118.279</value>
      <value name="cmassz">66.9694</value>
    </event>
    <event>
      <onset>2</onset>
      <duration>2</duration>
      <value name="volmean">759.218</value>
      <value name="cmassx">106.801</value>
      <value name="cmassy">118.242</value>
      <value name="cmassz">67.1636</value>
    </event>
    <!-- ... etc. ... -->
  </data>
</XCEDE>
```

## **7.1. Overview**

## **7.2. Examples**

## **7.3. Reference**

---

# Chapter 8. Assessments

## 8.1. Overview

Complete data storage and assessment specifications and descriptions are stored in XCEDE using the `assessment_t` and `assessmentDescItem_t` tag structures.

The description of the assessment questions and possible answer choices are specified in the protocol section of the schema whereas the actual assessment data for an acquisition are stored in the `assessment_t` tags

**assessment\_t.** The `assessment_t` tag extends the `abstract_data_t` tag to include information about the acquired assessment. The *name* element contains the assessment name which is unique within the document and links the acquired listing of assessment data back to the formal assessment definition optionally contained within the protocol description. The *dataInstance* element specifies the state of the acquired data. Specifically whether it is first entry, second entry, validated, unvalidated, etc.

**assessmentInfo\_t.** The `assessmentInfo_t` tag is derived from the `abstract_info_t` element and is used to store a description of the assessment

**assessmentItem\_t.** The `assessmentItem_t` tag is used to store the actual data captured by the assessment. The `assessmentItem_t` tag is composed of a `<valueStatus>` element which contains information about whether the subject declined to answer the question or why the data value might be missing. The `<value>` element stores the actual value of the assessment item as captured on the assessment itself. The `<normValue>` is used to store the normalized value for the element. The `<reconciliationNote>` is used to document whether the values have been reconciled if this data is part of multiple data entries. The `<annotation>` is used to annotate the assessment item. The `terminology_ag` reference is used to give contextual meaning to the question and link it with known ontologies and concepts.

## 8.2. Examples

The assessment example below shows both a formal assessment description stored in the `<protocol>` block and also the actual acquired assessment data

### 8.2.1. Formal Assessment Description

The formal description of each question for the assessment and possible answer choices

**Figure 8.1.**

```
<xcede:step ID="SES" name="Socio-Economic Scale" minOccurrences="1" maxOccurrences="1"
  required="true">
  <xcede:items>
    <xcede:item ID="ses_education_subject">
      <xcede:itemText>
        <xcede:textLabel location="leadText"
          value="What is the highest level of education or
professional training
          that you have achieved?"/>
        <xcede:textLabel location="trailText"
          value="Any trailing text might go here"/>
      </xcede:itemText>
      <xcede:itemChoice itemCode="1"
        itemValue="professional or graduate training (received
degree)"/>
        <xcede:itemChoice itemCode="2" itemValue="college graduate"/>
        <xcede:itemChoice itemCode="3" itemValue="some college (at
least one year)"/>
      </xcede:item>
    <xcede:item ID="ses_education_p_caretaker_prior_18">
      <xcede:itemText>
        <xcede:textLabel location="leadText"
          value="What is the highest level of education or
professional training that your primary caretaker until you were 18 years old has
achieved?"/>
        </xcede:itemText>
        <xcede:itemChoice itemCode="1"
          itemValue="professional or graduate training (received
degree)"/>
          <xcede:itemChoice itemCode="2" itemValue="college graduate"/>
          <xcede:itemChoice itemCode="3" itemValue="some college (at
least one year)"/>
        </xcede:item>
      </xcede:items>
    </xcede:step>
```

## 8.2.2. Actual Acquired Assessment Data

An instance of actual assessment data acquired on a subject during a protocol collection

**Figure 8.2.**

# Chapter 10. Terminology

## 10.1. Overview

The use of terminologies (and ontologies) are critical in the sharing of data. Ontologies specify the terms used to describe and represent areas of knowledge. They are commonly used by people, databases, and applications that have a requirement to share information about a subject. For example, the subject areas of medicine, real estate, and automobile repair all have specific ways of representing and communicating knowledge. Ontologies include computer-usable definitions of the basic terms describing the domain and the relationships between concepts. They encode knowledge within a domain and also knowledge that spans multiple domains. In this way, they make that knowledge reusable. For comprehensive information on ontologies and their use in biomedical science, please visit the National Center for Biomedical Ontology (NCBiO; <http://www.bioontology.org/>).

In the context of XCEDE, the use of terminologies is critical for data exchange. By specifying the exact terminological correspondences for data within XCEDE a user of the data is clear about what the data represents.

In order to accomplish this within XCEDE, two constructs are primarily used: `terminology_ag` and `terminologyString_t`. The `terminology_ag` attribute group defines the necessary information required to annotate a data item with its terminology correspondence. The `terminologyString_t` utilizes this attribute group and provides a basic type that can be utilized in the schema for data items that should have an associated terminology reference.

## 10.2. Examples

The use of terminologies is embedded within the XCEDE schema itself. For example, in regards to subject information, terminology strings are utilized to define the sex and species.

**Figure 10.1. Terminology String Instance**

```
<xs:complexType name="subjectInfo_t">
  <xs:complexContent>
    <xs:extension base="abstract_info_t">
      <xs:sequence>
        <xs:element name="sex" type="terminologyString_t" minOccurs="0"/>
        <xs:element name="species" type="terminologyString_t" minOccurs="0"/>
        <xs:element name="birthdate" type="terminologyString_t" minOccurs="0"/>
        <xs:any namespace="##other" minOccurs="0" maxOccurs="unbounded"/>
      </xs:sequence>
      <xs:anyAttribute namespace="##other" processContents="lax"/>
    </xs:extension>
  </xs:complexContent>
</xs:complexType>
```

As an example of the use of terminology strings, in the context of a subject detailed above, the following example shows how sex and species are represented for a human female subject.

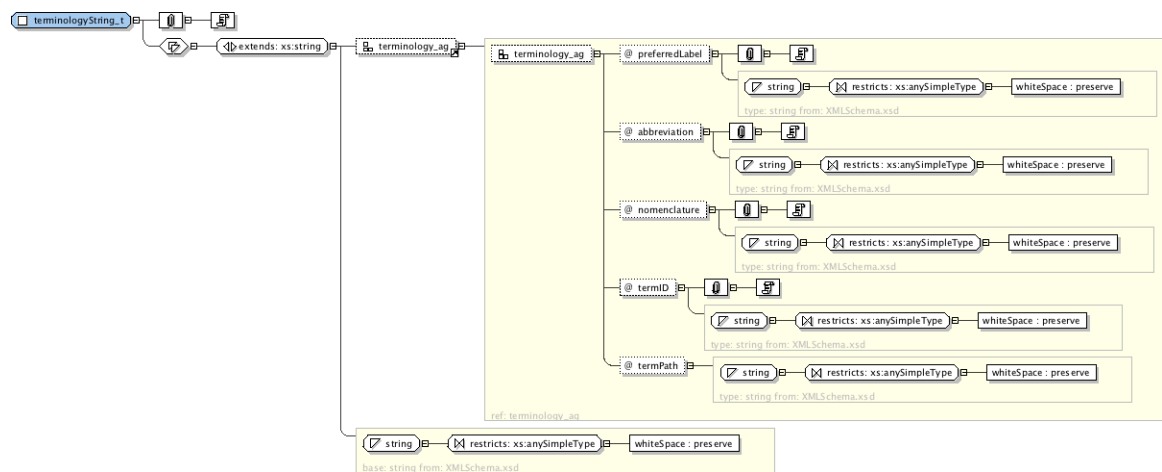

**Figure 10.2. Terminology String Instance**

```

<sex preferredLabel="Female" abbreviation="F" nomenclature="UMLS"
termID="C0015780" termPath="SNOMED CT Concept:Observable entity:General clinical
state:Gender:Female">f</sex>
<species preferredLabel="Human" abbreviation="human" nomenclature="BIRNLex"
termID="birn_org_anat:birnOrgAnatomy_366"
termPath="Thing:entity:continuant:independent_continuant:object:Biomaterial_object:Organismal_object:
species

```

## Part II. Using and Extending XCEDE 2

This section of the XCEDE 2.0 manual provides practical lessons on using the schema, as well as discussions on how to use W3C XML Schema to extend the core XCEDE 2 datatypes and how to integrate it into applications, databases and web services.

<xs:schema xmlns="http://www.xcede.org/xcede-2"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns:sch="http://purl.oclc.org/dsdl/schematron"
  xmlns:gml="http://www.opengis.net/gml" targetNamespace="http://www.xcede.org/xcede-2"
  elementFormDefault="qualified" attributeFormDefault="unqualified">
  <xs:import namespace="http://www.opengis.net/gml"
    schemaLocation="http://schemas.opengis.net/gml/3.1.1/base/gml.xsd"/>
  <xs:annotation>
    <xs:documentation>The XCEDE schema provides an extensive metadata hierarchy for
    describing and documenting research and clinical studies. The schema organizes
    information into five general hierarchical levels: a complete project; studies within
    a project; subjects involved in the studies; visits for each of the subjects; the full
    description of the subject's participation during each visit</xs:documentation>
    <xs:documentation>Each of these sub-schemas is composed of information relevant to
    that aspect of an experiment and can be stored in separate XML files or spliced into
    one large file allowing for the XML data to be stored in a hierarchical directory
    structure along with the primary data. Each sub-schema also allows for the storage
    of data provenance information allowing for a traceable record of processing and/or
    changes to the underlying data. Additionally, the sub-schemas contain support for
    derived statistical data in the form of human imaging activation maps and simple
    statistical value lists.</xs:documentation>
    <xs:documentation>XCEDE was originally designed in the context of neuroimaging
    studies and complements the Biomedical Informatics Research Network (BIRN) Human
    Imaging Database, an extensible database and intuitive web-based user interface for
    the management, discovery, retrieval, and analysis of clinical and brain imaging data.
    This close coupling allows for an interchangeable source-sink relationship between the
    database and the XML files, which can be used for the import/export of data to/from
    the database, the standardized transport and interchange of experimental data, the
    local storage of experimental information within data collections, and human and
    machine readable description of the actual data.</xs:documentation>

```

```

        traversal of this dimension.</xs:documentation>
    </xs:annotation>
</xs:element>
</xs:sequence>
<xs:attribute name="label" type="xs:string">
    <xs:annotation>
        <xs:documentation xml:lang="en">This is a label for the dimension. The first three
            spatial dimensions (or however many exist) must be labeled, in order, 'x', 'y',
            and 'z'. The first temporal dimension must be labeled 't'.</xs:documentation>
    </xs:annotation>
</xs:attribute>
<xs:attribute name="splitRank" type="xs:string">
    <xs:annotation>
        <xs:documentation>If this attribute exists, this dimension is a "split" dimension,
            and this dimension must be "merged" with one or more other dimensions (with the
            same label) before presenting the data to the application. This is useful, for
            example, if the data is stored in Siemens' Mosaic DICOM format, where slices of
            a 3-D volume are arranged to look like they are tiled onto a square 2-D area. In
            this case, what would normally be called the 'z' dimension has two forks, one
            that occurs before the 'y' dimension (the first row in the data covers the first
            row of several slices), and one that occurs after the 'y' dimension. If, as in
            this case, there are two or more dimensions that should be merged into one, both
            component dimensions should have the label 'z', but have splitRank attributes
            "1" and "2", which specifies the order in which all 'split' dimensions of the
            same label will be merged. After merging, the resultant 'z' dimension element
            should contain the same children of the highest-ranked split 'z' dimension,
            except for the 'size' element, which will be the product of the sizes of all 'z'
            split dimensions. The position of the resultant dimension should be the position
            of the highest-ranked 'z' split dimension. The data itself should also be
            reordered to reflect the new dimension structure.</xs:documentation>
    </xs:annotation>
</xs:attribute>
<xs:attribute name="outputSelect" type="xs:string">
    <xs:annotation>
        <xs:documentation xml:lang="en">In the same way that the 'splitRank' attribute
            allows you to specify dimensions that should be merged before presenting the
            data to an application, this attribute specifies a data filter along this
            dimension. If this attribute exists, it should contain a whitespace-separated
            list of indices (indexed starting at 0). Only data points along this dimension
            that occur in the index list should be presented to the application. Likewise,
            the 'size' of the dimension, after selection, should be updated to reflect the
            new size of this dimension (which should be the number of indices in the content
            of this attribute).</xs:documentation>
    </xs:annotation>
</xs:attribute>
</xs:complexType>
<xs:complexType name="mappedBinaryDataDimension_t">
    <xs:complexContent>
        <xs:extension base="binaryDataDimension_t">
            <xs:sequence>
                <xs:element name="origin" type="xs:float" minOccurs="0">
                    <xs:annotation>
                        <xs:documentation xml:lang="en">A value assigned to the first data
                            element along this dimension. For example, if this dimension
                            corresponds to "time", this element could store the time
                            corresponding to the first data element. If this is a
                            two-dimensional projection of the surface of the Earth, and this
                            dimension takes you around the Earth parallel to the equator, this
                            value could be the degrees longitude. For MRI data, this is the
                            single coordinate on the Left-to-Right, Posterior-to-Anterior, or
                            Inferior-to-Superior axis to which this dimension most closely
                            matches (see 'direction' element and 'rasOrigin' element in
                            'mrImageDataResource_t').</xs:documentation>

<xs:element name="datapoints" minOccurs="0">
  <xs:annotation>
    <xs:documentation xml:lang="en">The content of this element is either
    (1) a whitespace-separated list of values, or (2) a list of 'value'
    elements, that can be used as a label for each data point along this
    dimension. The values can be numbers representing points on an axis
    (this is the typical case), text strings, coordinate tuples, etc.
    Any datapoint label that includes whitespace (coordinate tuples
    included) must be encapsulated within a child 'value' element. If
    this element is missing, it is assumed that labels can be calculated
    using information in other fields (such as 'origin', 'spacing',
    etc.). This element is particularly useful for dimensions with
    irregular spacing.</xs:documentation>
  </xs:annotation>
